ASSEMBLY OF NEUROSCIENCE TO THE MODEL OF MIND

Pathma A Liyanage

ABSTRACT

In current, there was several mind models developed as cognitive architectures and their main focus is to explain mind functions. However, few architectures explain the neural basis of the mind. Also in neuroscience explain the neural basis of the brain and is directly related to the mind. The study objective was to identify a mind model with a neural basis established in the model. Therefore the study uses a systematic review of existing literature to find a mental model with a neural basis. For that study use articles within databases of PUBMED and Google scholar. Only English-language articles were selected, but no year restriction was applied.

Previous literature about cognitive science, mind models, fundamentals of neuroscience, developmental neuroscience, visual and auditory neuroscience was considered for the study. The data was critically appraised by independent two reviewers to eliminate the risk of bias. Then articles characterized motivations, major assumptions, relationships to neurobiology, modules, working memory, long-term memory, goals, learning, standard cognitive cycle, and model creation. Then best-described mind functions and neural structures synthesis to identify neural circuits assembled mind model.

International module, declarative module, visual module, manual module, goal buffer, retrieval buffer, visual buffer, manual buffer, a procedural module with matching, selection, and execution identified as main functions in mind model. Temporal/Hippocampus, VLPFC, aPFC, DLPFC, occipital, parietal cortex, cerebellum, motor cortex, basal ganglia, striatum, pallidum, and thalamus was the associative neural areas of the brain. This explained sensory inputs to brain structures of the frontal cortex, hippocampus & septum, sensory cortex, thalamus, amygdala, midbrain & hypothalamus, hindbrain, and spinal cord. Also reveal the interaction of brain structures of the sensory cortex, hypothalamus, thalamus, amygdala, hippocampus, and working memory of mPFC and dIPFC. In the mind model, the main inputs are taken from the posterior cortex. Then active maintenance is done by the frontal cortex; episodic memory provides by the hippocampus; action selection is done by basal ganglia.

This reveals the mind model with neurological circuit assemblies to it. The final model will limit to features of only available cognitive architectures of PUBMED and Google databases in English.

1.Introduction to the Mind model

The consciousness, mental functions, events, properties, nature of mind, and their relationship to the physical body explains the philosophy of mind. Understanding the scientific, philosophical, and psychological view of the mind-brain system is the most complex and challenging subject.

According to the Sigman Freud topographical model of the mind, there are at least 3 levels of mind namely the conscious mind, the subconscious mind, and the unconscious mind. He explained it using an analogy of an iceberg as follows.

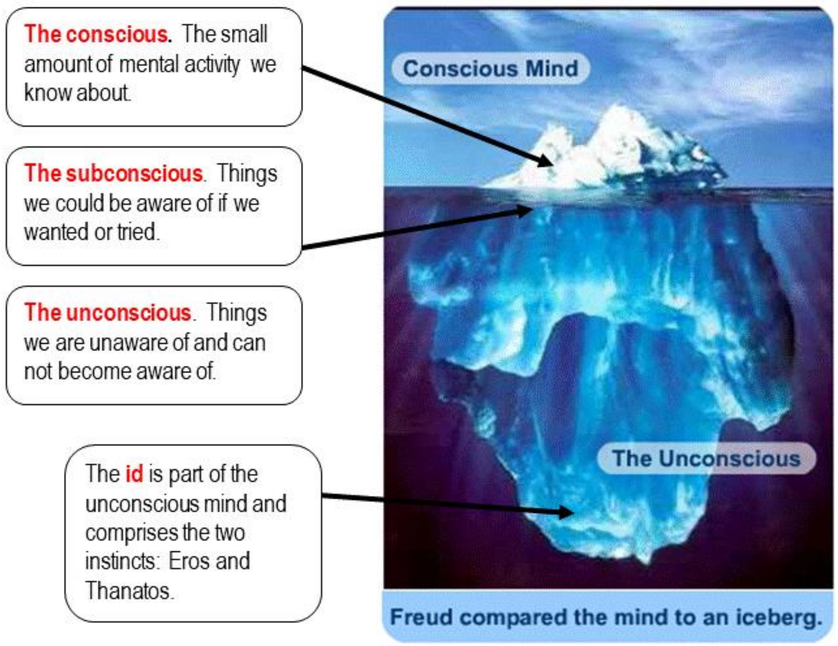

Figure 1 – The topographical model of mind by Sigmund Freud

Image credit - https://www.simplypsychology.org/Sigmund-Freud.html

According to him, the tip of the iceberg represents the conscious mind that has mental activities which we are known. The subconscious mind consists of all which can recall by memory.

However, the most significant region is the unconscious mind. It includes many memories and thoughts that we are not aware of, Strangor et al., (2014).

The structure of a cognitive architecture explains component organization using information and processing, and how flowing of information between components.

The standard model of mind explains that the mind has distinct functionalities and is built of independent modules, and is not an undifferentiated pool of information and processing, Laird et al.,(2017).

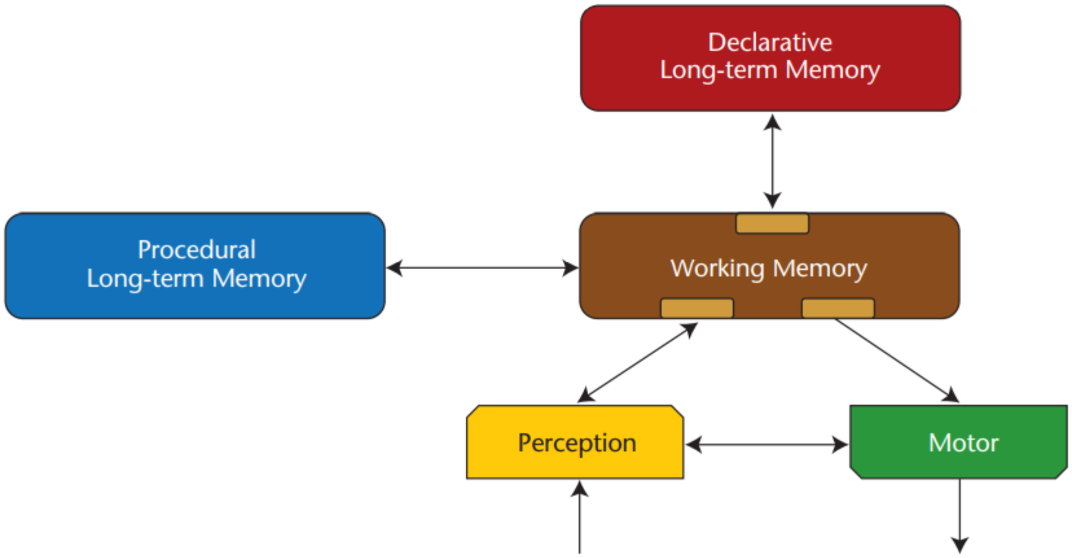

Figure 2: The structure of the standard model

Image Credit: Laird et al.,(2017)

The scientific study of the nervous system is called neuroscience. It understands the fundamental and emergent properties of neurons and neural circuits by combining physiology, anatomy, molecular biology, developmental biology, cytology, mathematical modeling, and psychology.

Therefore the model of a mind is directly related to neuroscience. Each function of a mind has a certain neural circuit. Which explains the physical basics of the mind.

According to neuroscience brain functions of the mind are as follows.

- Frontal lobe: ability to move, reasoning and problem solving, part of language and emotions. It is mainly involved in executive, personality, and decision-making functions.
- Parietal lobe: sensitivity, perception, pain, pressure, temperature and touch, external sensory perceptions (hands, feet, etc.).
- Occipital lobe: production of images and where we see.
- Temporal lobe: visual tasks such as face recognition. Also receives and processes information from the ears, contributes to balance, and regulates emotions and motivations such as anxiety, pleasure, and anger.

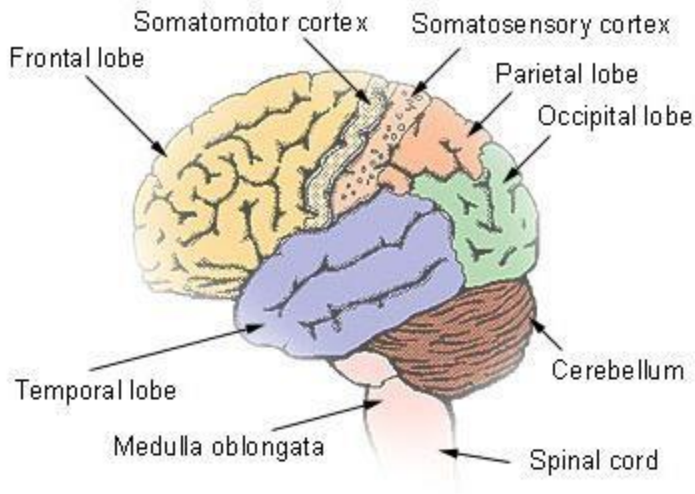

Figure 3. Brain lobes

- The main function of the hippocampus is to mediate the generation and recovery of memories.

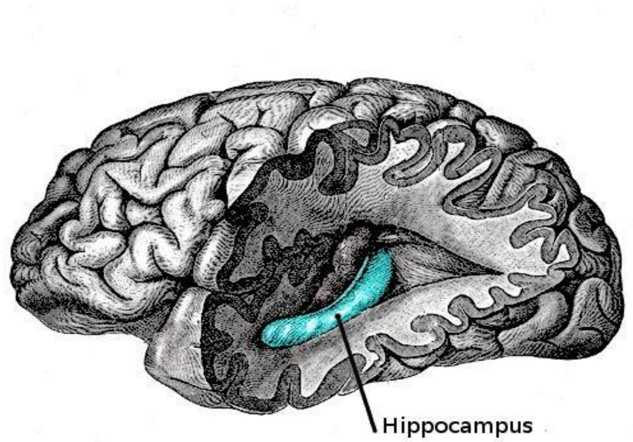

Figure 4. Hippocampus

- The Limbic system is responsible for processing and regulating emotions, the formation and storage of memories, sexual arousal, and learning.

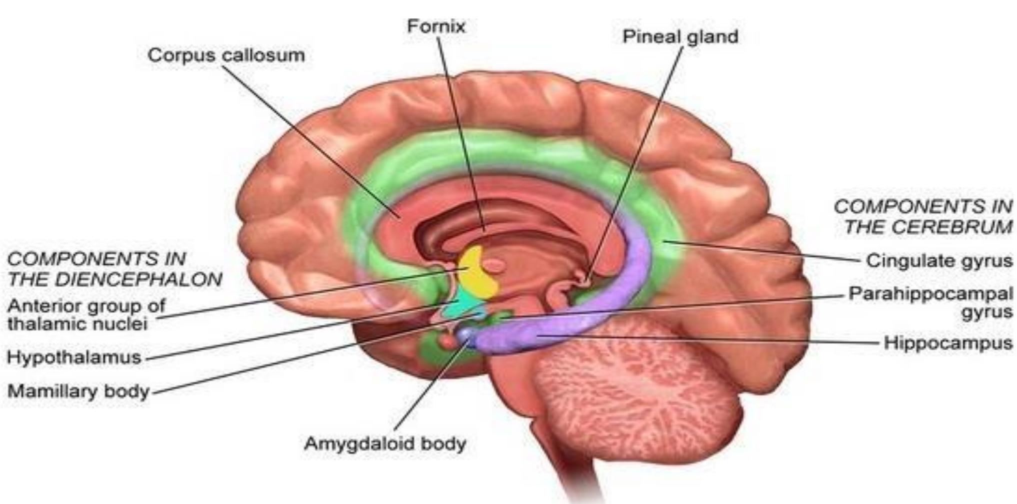

Figure 5. Limbic system

- The neocortex is responsible for computations of attention, thought, perception, and episodic memory.

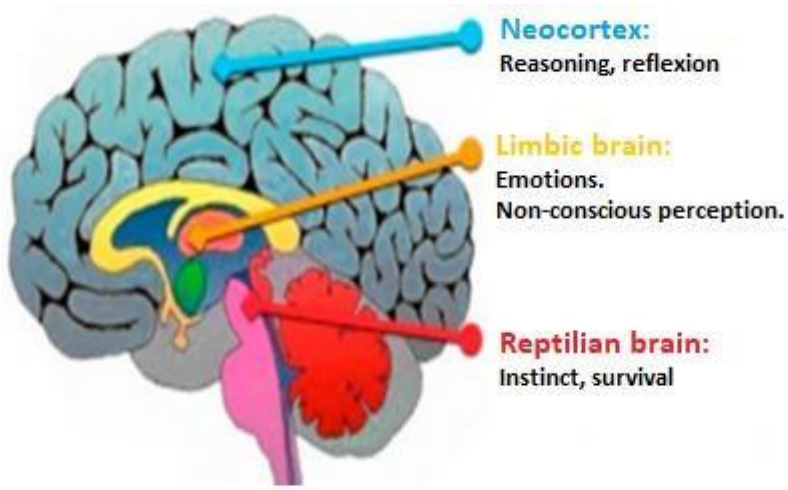

Figure 6. The neocortex

- The cerebral cortex refed to meanings.

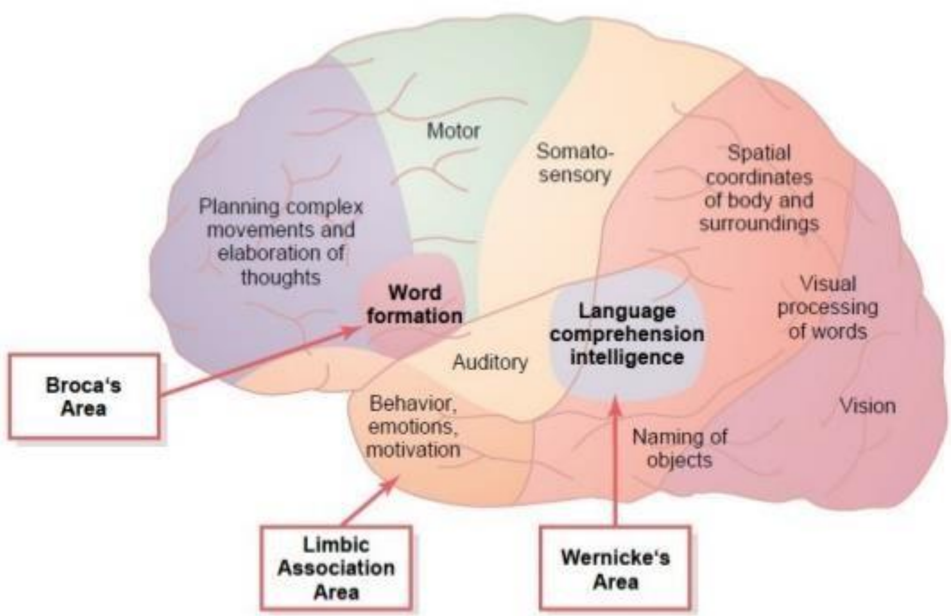

Figure 7. Functional areas of the cerebral cortex.

- The prefrontal cortex, posterior partial cortex, fusiform gyrus, and reticular formation leads to attention.

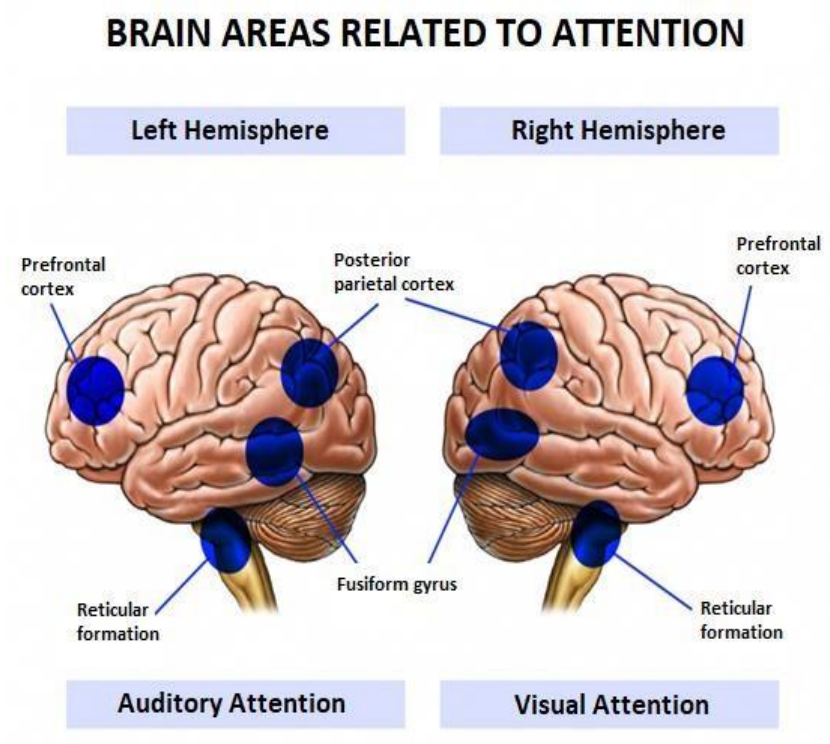

Figure 8: Prefrontal cortex, posterior partial cortex, fusiform gyrus

Cognitive science studies mental functions of perception, attention, working memory, long-term memory, producing and understanding language, learning, reasoning, problem-solving, and decision making.

Some mental models have developed as cognitive architectures and need to study those architectures to get a broad view of a mental model.

Theory of Mind (ToM) has explained the idea that meta representation ability of mental states in specific neural circuitry depends on a domain-specific cognitive subsystem: a Theory of Mind Module, Gerrans and Stone, (2008). In simply ToM is the ability to understand the difference of mental status from oneself to others, Zeng et al.,(2020)

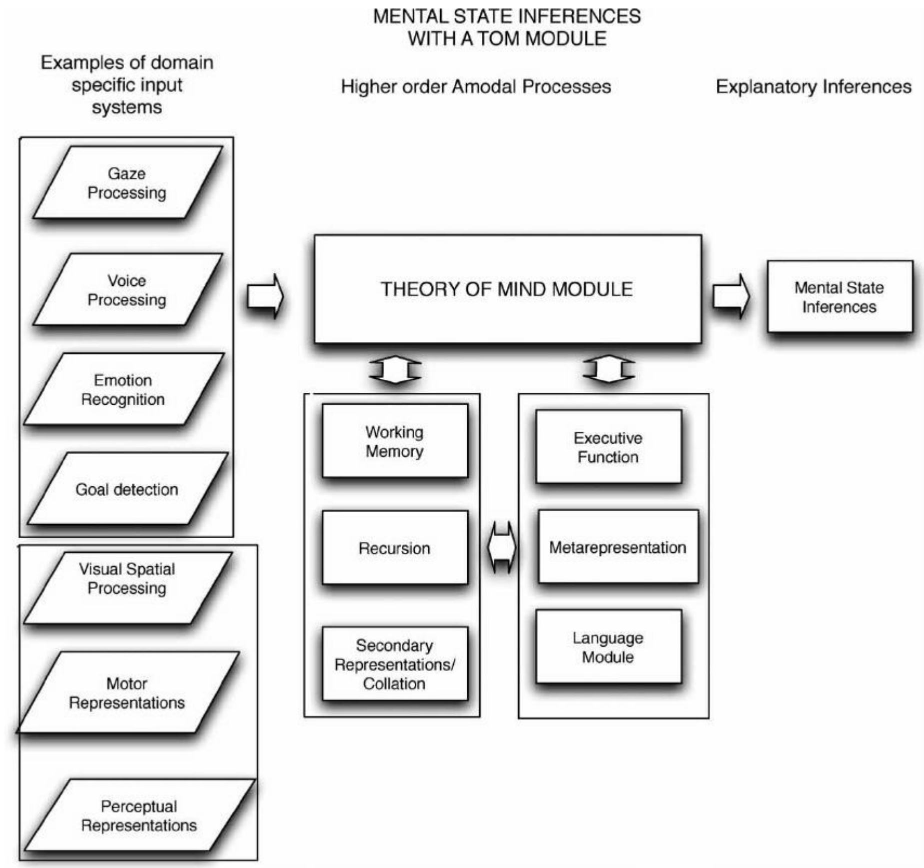

Figure 9. Theory of Mind module

Image credit: Gerrans and Stone, (2008)

Mind models are providing answers for the number of questions which is related to our mind. The way we think, the way people understand knowledge, and the way we anticipate the world and make decisions are represented by mind models.

According to Johnson-Laird (2004), perception and linguistic comprehension yield mind models. He also explained that thinking and reasoning are the internal manipulations of mental models. In a simple mind models are representations in the mind of real or imaginary situations, Laird et al., (2004).

Extensive studies of mental models are carried out since the models are important to understand the knowledge involved and would be able to stimulate and test it.

Some theorists and psychologists explored their knowledge to prove the existence of mind models while other suggested refinement in the existing mental model theory. Gentner, D. and Stevens, A., (2014).

According to the model theory, everyday reasoning depends on the simulation of events in mind models. It depends on simple primary assumptions as follows, Laird et al., (2006).

- Each model represents a possibility
- Models explain deduction, induction, and explanation
- Mind models represent only what is true

- Models are explain as iconic as far as possible
- Procedures for reasoning in a mental models rely on counterexamples.

Young (1983) suggested eight tentative types of mind models namely strong analogy, surrogate, mapping, coherence, vocabulary, problem space, psychological grammar, and commonality, Young et al., (1983).

However Young does not mention the origin of the model types and their evaluation criteria. Later Laird (1989) cautions that all model distinctions may be artificial for they may represent the same reality, Laird et al.,(1989).

Cognitive scientists may argue that the mental models are constructed as a result of perception (becoming aware of something by seeing), imagination (forming new ideas), knowledge, and the hearing or action of understanding something by using other senses by written or spoken communication (comprehension).

Within the research, field scientists have identified several problems challenges, and confusions related to the construction of mental models.

Norman reports concluded that the mental models are fragmentary and worse, Norman et al., (1983).

1.Mental models are incomplete
2.Ability of the peoples to run their models are severely limited
3.Models are unstable
4.Mind models do not have firm boundaries.
5.Mind models are unscientific
6.Mind models are parsimonious often.
7.People do extra physical operations rather than mind planning.

Due to the dynamic nature of mental models, they seem to be more process than outcome basis.

Although mind model research had begun 3-4 decades ago, several issues remain to be solved. More work is to be done for the clarification of definitions even.

It is better to do studies on what learning concepts help to explain the mind models phenomena. Also, researches should be carried out to find the answers to whether mind models are transitory or more permanent, how does mind models research relate to the current thinking in brain psychology.

2.Objectives

In neuroscience studies, the nervous system explains the physical or biological view of the mind. In cognitive science studies mental functions and explains the logical view of the mind. To get a clear picture of a mental model both of physical or neurological view and logical or cognitive view needed. A cognitive architecture should be biologically structures assembled to explain insights from what is known from the brain science of humans. Such architectures should model using processes of cognitive neuroscience. Also, the model of mind is expected to contribute from biologically inspired cognitive architectures. This proposes that the mind model dynamically and cyclically form such a network according to neuroscience. Therefore, cognitive architecture should be biologically inspired to implement conceptually and computationally.

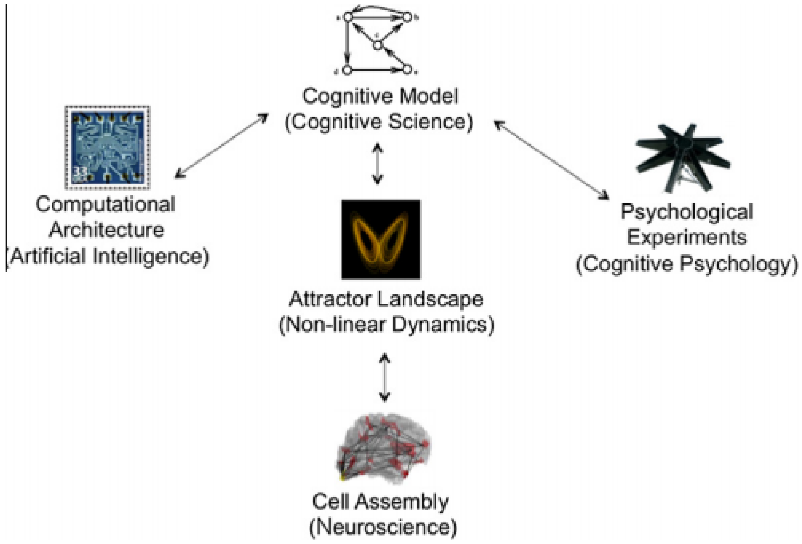

Figure 10. Theoretical levels of abstraction

Image credit: Franklin, (2012)

This revealed how is the grounding of the model of the mind in neuroscience to be accomplished. To ground these perceptual symbols representation in the underlying neuro science cell assemblies, but rather wings of chaotic attractors in an attractor landscape. Therefore this study aims to develop a mental model with mental function as well as neural circuits. It can be explained as a neurologically inspired cognitive model of a mind.

The study uses a systematic review of literature developed in mind models, cognitive architectures, neurological models and combines those to get a clear picture of the mind.

3.Materials and methods

3.1. Protocol and registration

The method used to develop a neurologically inspired mind model was a systematic review. This systematic review use literature related to mental models, cognitive architectures, and neuroscience models will make assembly of neuroscience to the model of the mind.

The protocol used for a systematic review is PRISMA-P. This systematic review is for developing a mental model using literature, and not for health-related studies. Therefore no need to register in the PROSPERO registry.

3.2. Eligibility criteria

Previous literature about cognitive science, mind models, fundamentals of neuroscience, developmental neuroscience, visual and auditory neuroscience was considered for the study. There is no year restriction, but only English language literature is considered for the study.

3.3. Information sources

Published research articles about cognitive science, mind models, fundamentals of neuroscience, developmental neuroscience, visual and auditory neuro science used as information sources and those available in google scholar, PUBMED databases.

3.4. Search

Literature explained the model of mind used in this study. Search terms included as follows: "cognitive architectures", "mental models", "fundamental of neuroscience", "developmental neuroscience", "visual and auditory neuroscience", "biologically inspired cognitive architectures".

3.5. Study selection

According to the search criteria, information databases were searched and initial literature was identified. After identification of initial literature, duplicates were removed. Then record screening was done by 2 independent reviewers (myself and Dr. Dayangi Hemalika) for inclusion criteria were met in the duplicate removed literature. The literature identified by both reviewers was selected for continuation. Then full-text articles were assessed for eligibility using eligibility criteria. Then n articles were selected for qualitative synthesis. From the systematic reviewing of literature of mental models, the best model or combination of models was selected for further analysis.

3.6. Data collection process

When the search strings were applied to all databases, the result articles were downloaded. The results were imported for duplicate removal. Duplicate removed articles submitted to a screening process by two independent reviewers. Then articles were assessed according to the eligibility criteria. Selected articles from assessing eligibility criteria, submitted to qualitative synthesis.

3.7. Data items

Each functional category of the selected mind model is considered a data item. Also neurologically path identified by the systematic review was a data item. Motivations, major assumptions, relationships to neurobiology, modules, working memory, long-term memory, goals, learning, standard cognitive cycle, and model creation were extracted from each article Schierwagen, (2010).

3.8. Risk of bias in individual studies

The data was critically appraised by independent two reviewers. The record was appraised by 2 independent reviewers (myself and Dr. Dayangi Hemalika) for inclusion criteria were met in the duplicate removed literature. This was done at the outcome level. Articles identified by both reviewers were selected for continuation.

3.9. Summary measures

There are 290 articles identified in searching databases of PUBMED and Google Scholar. Also, an additional record of 10 articles was identified in other sources of books. Then those identified 300 articles submitted to duplicate removal. After duplicated removal, 200 articles were identified as unique articles. Then initial screening was done using 2 independent reviewers. From the screened articles, 85 articles were excluded, and the remaining 115 full-text articles were submitted to eligibility assessment.

Articles about cognitive science, mind models, fundamentals of neuroscience, developmental neuroscience, visual and auditory neuroscience were considered as the eligible articles for the study. There is no year's restriction, but only English language articles are considered for eligibility.

From assessed full-text articles, 9 full-text articles were selected for synthesis. Those selected articles described cognitive architectures of mental models and neurological paths related to cognitive functions.

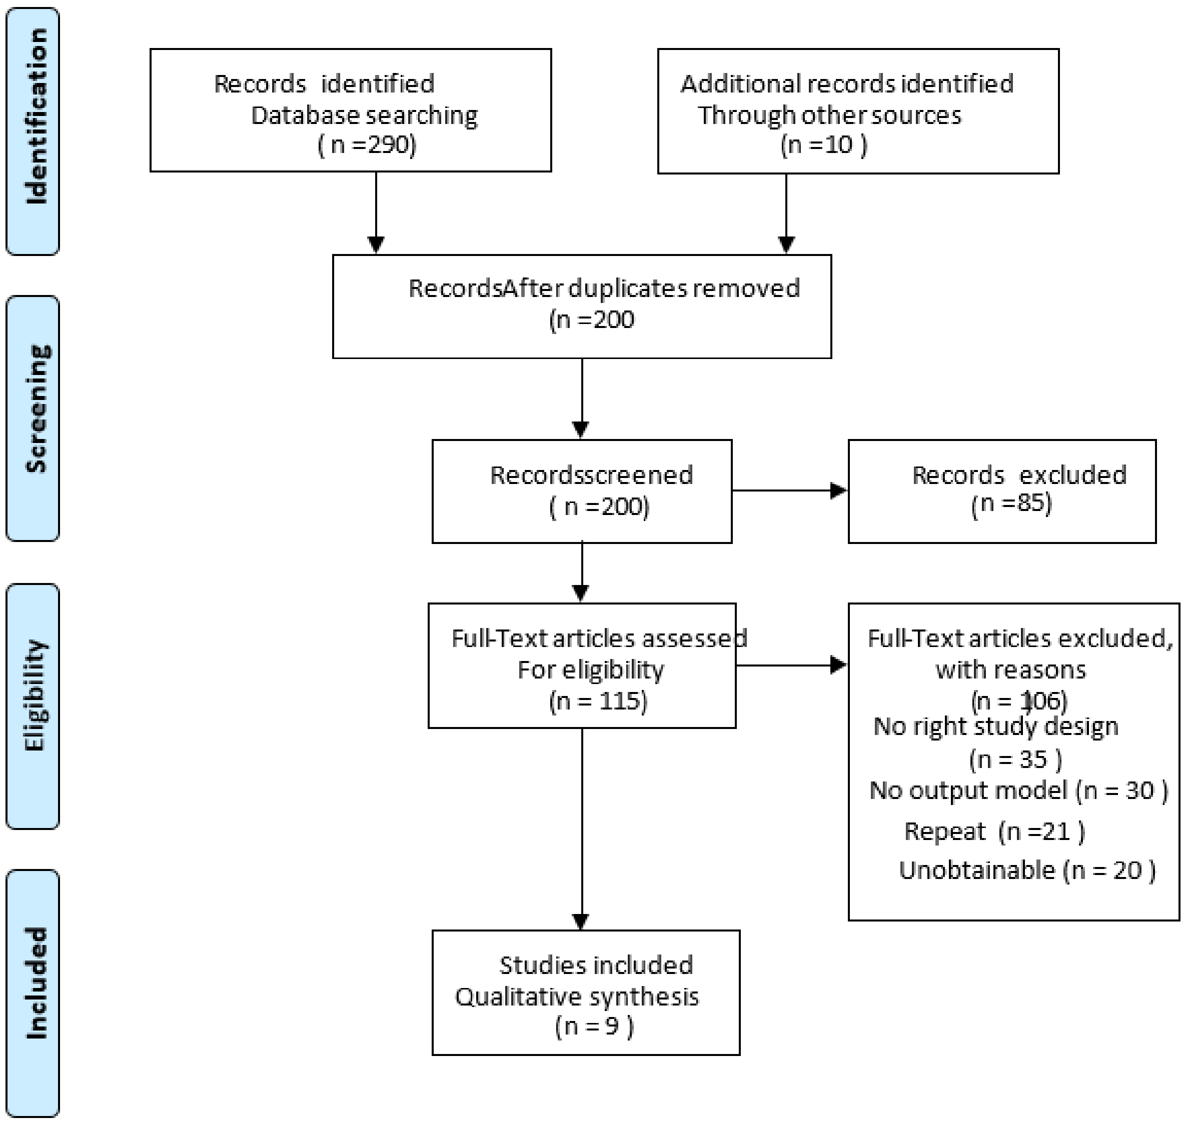

Figure 11. PRISMA diagram

3.10. Synthesis of results

A cognitive architecture should be biologically structures assembled to explain insights from what is known from the brain science of humans. Such architectures should model using processes of cognitive neuroscience. Also, the model of mind is expected to contribute from biologically inspired cognitive architectures. This proposes that the mind model dynamically and cyclically form such a network according to neuroscience. Therefore, cognitive architecture should be biologically inspired to implement conceptually and computationally.

Each function of the selected mind model will combine neurological path in articles of fundamental of neuroscience, developmental neuroscience, visual and auditory neuroscience for assembling the selected mind model to neuroscience.

This included functional analysis and structural analysis of the mind, Schierwagen, (2010).

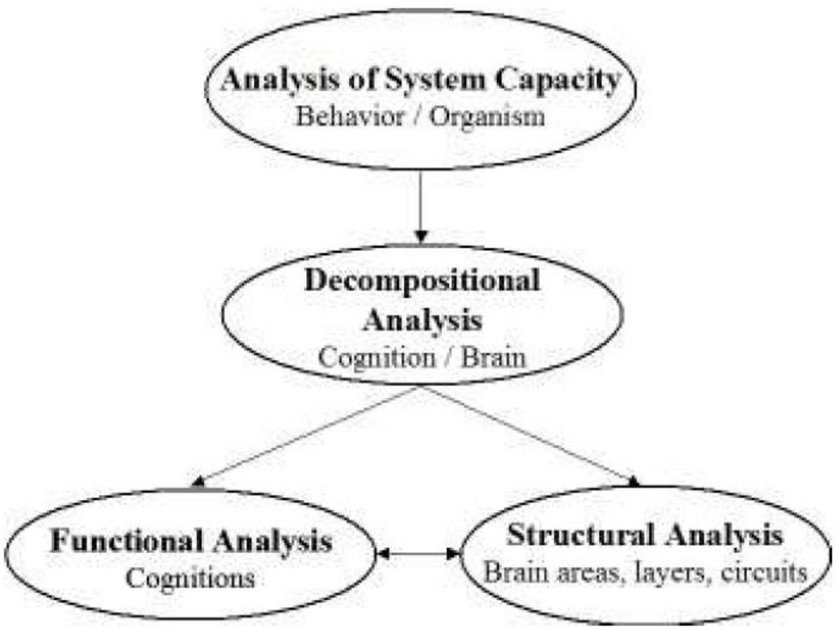

Figure 12: Analysis of brain and cognition

Image credit: Schierwagen, (2010)

This will reveal how is the grounding of the model of the mind in neuroscience to be accomplished. To ground these perceptual symbols representation in the underlying neuroscience cell assemblies, but rather wings of chaotic attractors in an attractor landscape.

4.Results

4.1.Study selection

There are 290 articles identified in searching databases of PUBMED and Google Scholar. Also,an additional record of 10 articles was identified in other sources of books. Then those identified 300 articles submitted to duplicate removal. After duplicated removal, 200 articles were identified as unique articles. Then initial screening was done using 2 independent reviewers. From the screened articles, 85 articles were excluded, and the remaining 115 full-text articles were submitted to eligibility assessment.

Articles about cognitive science, mind models, fundamentals of neuroscience, developmental neuroscience, visual and auditory neuroscience were considered as the eligible articles for the study. There is no year restriction, but only English language articles are considered for eligibility.

From assessed full-text articles, 9 full-text articles were selected for synthesis. Those selected articles described cognitive architectures of mental models and neurological paths related to cognitive functions.

4.2.Study characteristic

4.2.1.LIDA cognitive architecture

LIDA consists of sophisticated action selection, motivation by emotions, and attention mechanism of centrally important, and multimodal instructionalist and selectionist learning. The LIDA architecture grounded a variety of modules and processes in cognitive science and cognitive neuroscience, each with its effective representations and algorithms. LIDA has explained motivation, emotion, attention, and autonomous learning in cognitive agents, Franklin et al., (2012).

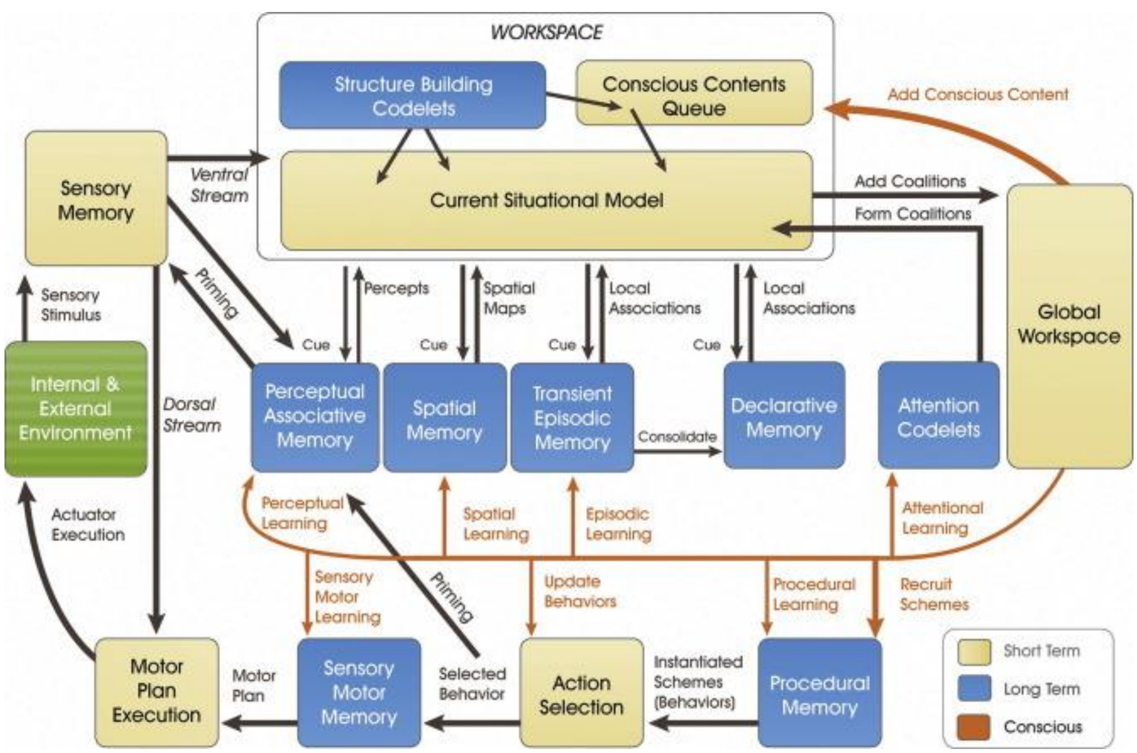

Figure 13: LIDA cognitive cycle diagram

Image credit: Franklin et al., (2012)

4.2.2.Soar cognitive architecture

Soar is also consisted of a rule-based procedural memory and includes a set of asynchronous internally parallel modules. Soar is organized around a global working memory and long-term memory, Laird, (2008). The long term memory consists of procedural, semantic, and episodic memories.

Soar has purely symbolic representations of knowledge relied on a minimal number of architectural modules. The Soar cognitive architecture approach consists of decision procedure, reinforcement learning, chunking, semantic learning, and episodic learning.

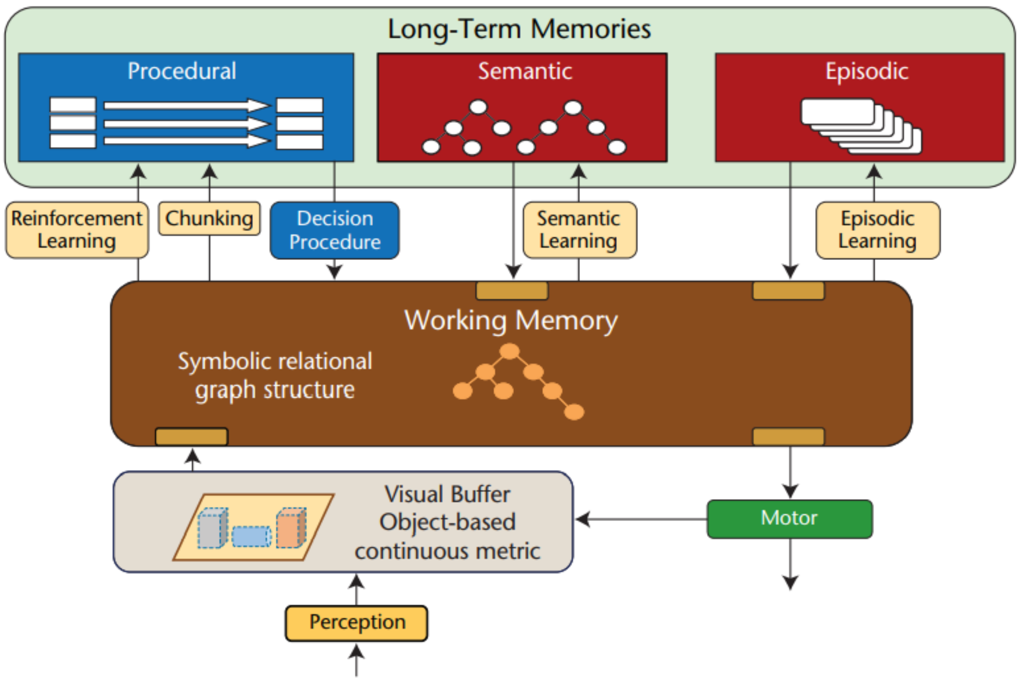

Figure14: Soar cognitive architecture

Image credit: Laird, (2008)

4.2.3.Sigma cognitive architecture

Sigma (Σ) cognitive architecture consists of long-term memory and working memory. Sigma long-term memory includes procedural and declarative memory. And sigma working memory includes perception and motor, Rosenbloom and Demski, (2016).

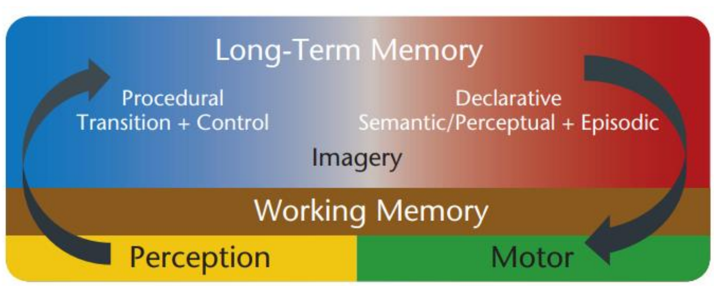

Figure 15: Sigma cognitive architecture

Image credit: Rosenbloom and Demski, (2016) 4.2.4.SAL cognitive architecture

The SAL cognitive architecture is a combined model of two well-established architectures of a hybrid symbolic-subsymbolic cognitive architecture: ACT-R, and, a neural architecture: Leabra, Jilk, et al., (1983). These vastly different component architectures have a combined view of the brain, the mind, and behavior. Furthermore, both of these architectures are a single level of abstraction unable to capture the required behavioral richness. However, both architectures are internally pluralistic and recognize those models.

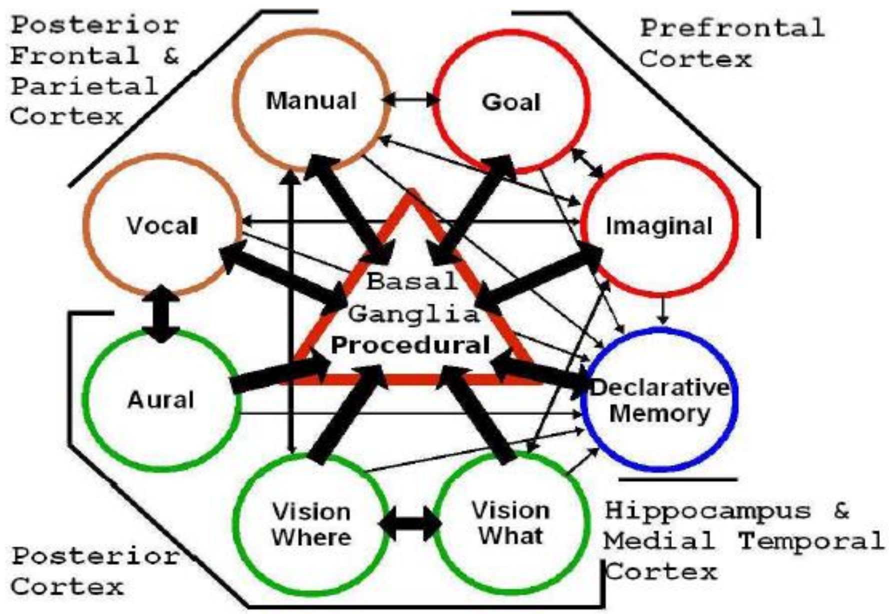

Figure 16: Overview of SAL architectural organization

Image credit: Jilk et al., (1983)

4.2.5.ACT-R(Adaptive Control of Thought—Rational) Cognitive architecture

ACT-R cognitive architecture consists of a set of independent modules that function around the central procedural module. It can describe the processes from perception through to action for a wide range of cognitive tasks. It can be used to identify models of specific tasks, which explains exact predictions in the form of response times and accuracy measures. It can address brain-wide activation patterns since ACT-R provides a model of all the components in task performance, Borst and Anderson, (2017).

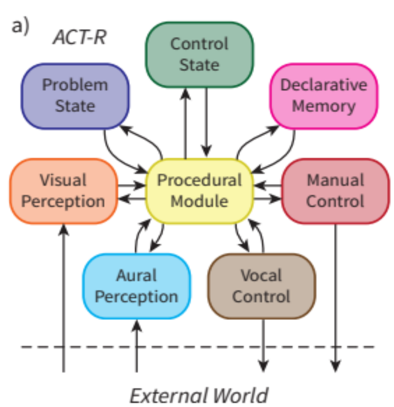

Figure 17: Main modules of ACT-R

Image credit: Borst and Anderson, (2017)

4.2.6.EPIC cognitive architecture

EPIC architecture explains the basic building blocks of a cognitive architecture as cognitive, perceptual, motor, and knowledge representation Judwig, (2005).

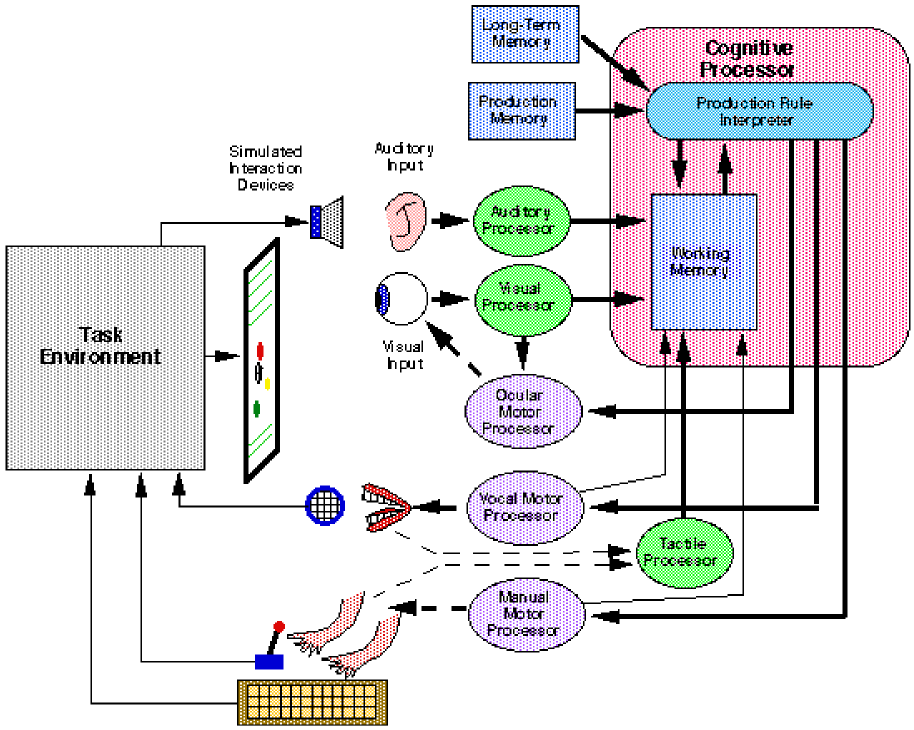

Figure 18: EPIC Architecture

Image credit: Judwig, (2005)

4.2.7.Leabra cognitive architecture

Leabra architecture tries to simulate neural activation function as a neocortical pyramidal neuron, neural learning rule as a function of neural activity, the inhibition function as inhibitory inter neurons on network dynamics, Jilk et al., (1983).

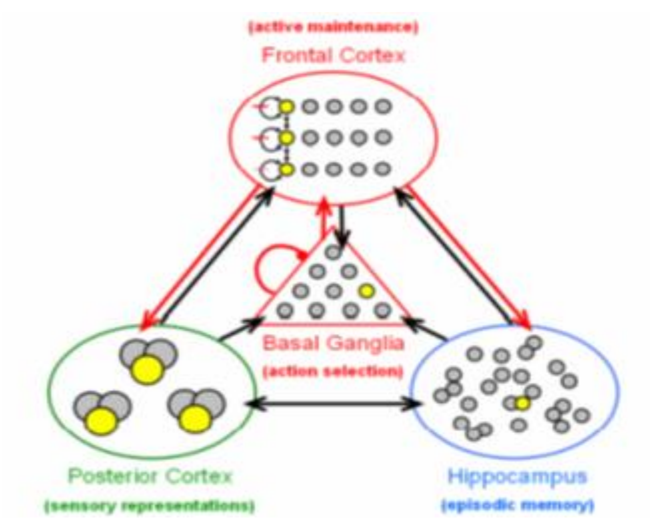

Figure 19: Overview of Leabra architectural organization

Image credit: Jilk et al., (1983)

4.2.8.Cognitive – Affective architecture

Cognitive – Affective architecture combines affective of short term, medium-term, and long term characteristics to the architecture Perez et al., (2016). It includes emotions, mood, and personality. It consists of main modules of procedural memory, working memory, semantic memory, episodic memory, decision procedure, and perception module.

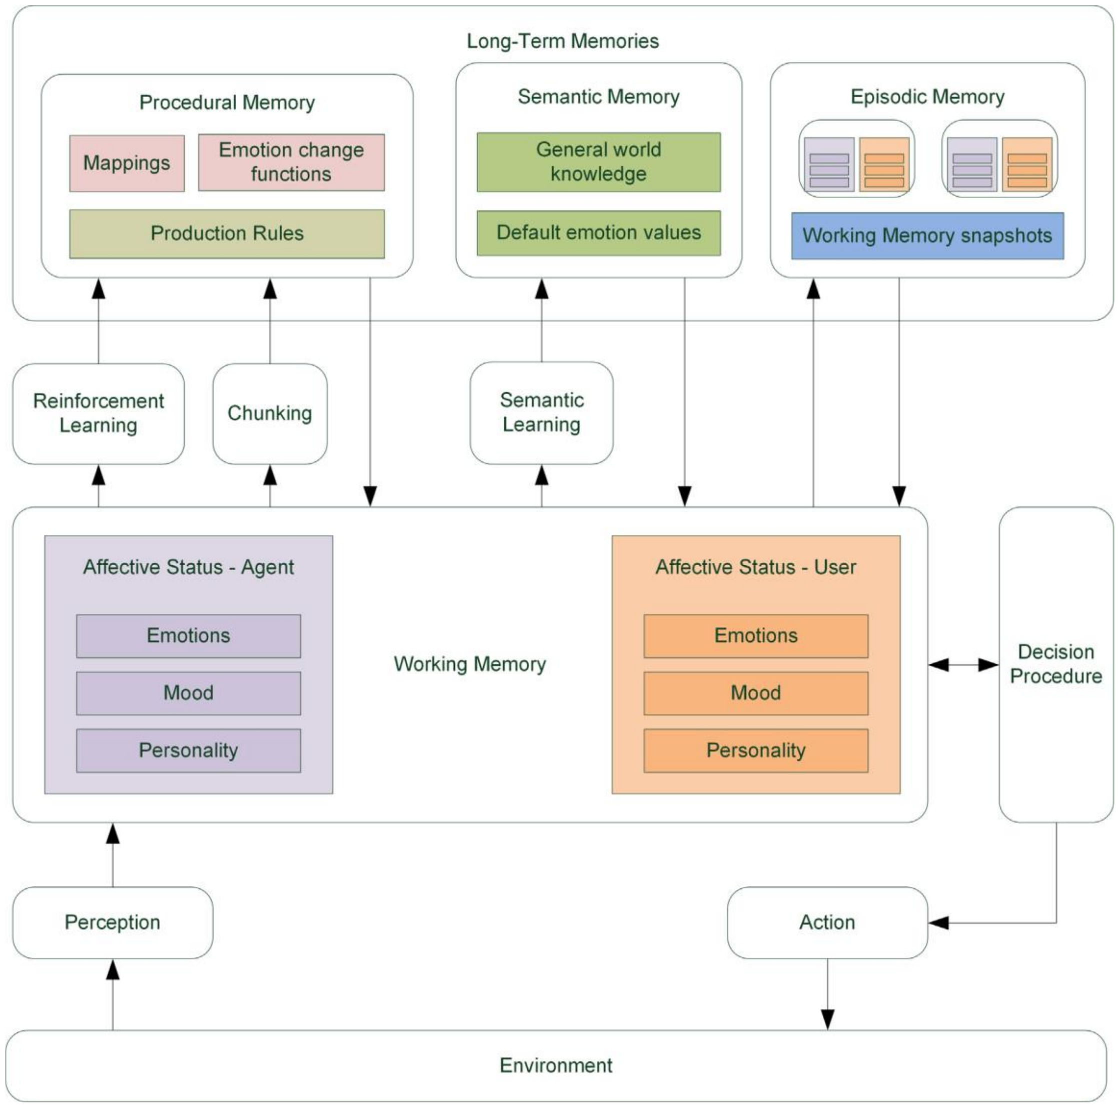

Figure 20: Affective architecture

Image credit: Perez et al., (2016)

4.2.9.An embodied cognitive-affective architecture

Cognitive affective architecture embodied emotions and organisms to the cognitive architecture, Ziemke and Lowe, (2008). . This explains (1) the emotional and biological mechanisms that come with the organismic embodiment of living cognitive systems, (2) models of these mechanisms can be usefully integrated with artificial cognitive systems architectures.

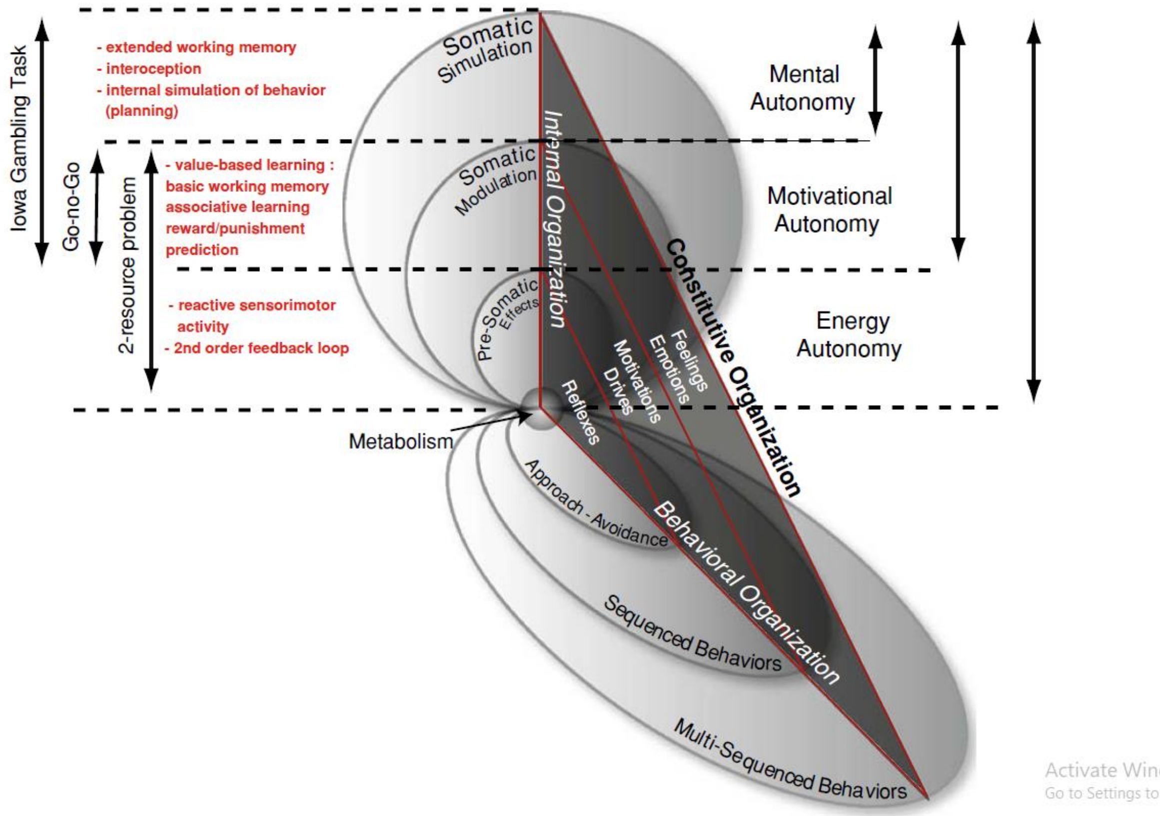

Figure 21: An embodied cognitive-affective architecture

Image credit: Ziemke and Lowe, (2008)

4.3.Risk of bias within studies

Articles were accessed by two individual reviewers and there are no significant differences in the article reviewed by two revivers.

4.4.Results of individual studies

The detailed interpretation of features of eligible literature is as follows.

Motivations	LIDA, Franklin et al. (2012)	Soar, Laird (2008)	Sigma, Rosenbloom and Demski (2016)
	the mechanism, continual, incremental and online learning	Problem-solving and learning	generic cognition, grand unification, functional elegance, and sufficient efficiency
	SAL, Jilk et al. (1983)	ACT-R, Borst and Anderson (2017)	Epic, Judwig (2005)
	comparative anatomy, superior functional capabilities through tighter, principled integration	Problem solving and memory	Multiple task performance and embodied cognition
Major Assumptions	LIDA	Soar	Sigma
	functional consciousness	Representing cognition related to problem spaces. The uniformity principle.	Reformulates an existing capability to be simpler and more elegant.
	SAL	ACT-R	Epic
	attempt to synthesize and integrate the theory of neural function, network behavior, and representation, theory of symbolic	Chunks activation as declarative knowledge. Limitation of Central processing.	Embodied cognition. The simplest assumptions make at first and refined in the later stage.

	and sub-symbolic decision-making, modular architectural organization and representational activation and organization		
Relationship to Neurobiology	LIDA	Soar	Sigma
	LIDA is a model of minds, not a model of brains	Soar does not address the features of brain areas.	Sigma does not directly address features to brain areas.
	SAL	ACT-R	Epic
	anatomy of the basal ganglia try to map the details of the production rule cycle	ACT-R tries to map the particular functional areas of the human brain into the modules and their features of ACT-R.	Epic does not directly address features to brain areas.
Modules	LIDA	Soar	Sigma

Semantic memory, episodic memory, procedural memory, image memory, working memory, perception, and motor.

	procedural memory		
	SAL	ACT-R	Epic
	declarative memory, imaginal, goal, manual, vocal, aural, vision where vision what	Motor, goal, declarative memory, perceptual and cognitive.	Motor, cognitive, And perceptual.
Working Memory	LIDA	Soar	Sigma
	LIDA short-term memory consists of sensory memory, conscious content cue, action selection, current situational model, action selection, current situational model, and transient episodic memory.	Working memory capacity is unlimited. It consists of problem states, where states are attribute or value pairs, but the current state is related to the duration of some working memory elements.	Sigma working memory was based on working memory of object-attribute value triples. Working memory could be changed when firing rules in long-term memory.
	SAL	ACT-R	Epic
	The SAL cognitive architecture is a combined model of ACT-R and Leabra, therefore the working memory feature of ACT-R is applicable for SAL as follows. Working memory	Working memory is both the procedural as well as productions memory and the contents of the module buffers. There is unlimited duration and capacity for	The goals and state of production rules consist in the cognitive section of the general working memory, along with general task information. It contains unlimited capacity and duration.

	is both the procedural as well as productions memory and the contents of the module buffers. There is unlimited duration and capacity for declarative, productions, and the sub-symbolic aspects of productions and the memory. Their trieval buffer size of one chunk is limit the number of declarative objects.	declarative, productions, and the sub-symbolic aspects of productions and the memory. Their trieval buffer size of one chunk is limit the number of declarative objects.	
Long Term Memory	LIDA	Soar	Sigma
	LIDA long term memory consists of perceptual associative memory, special memory, declarative memory (auto biographical memory and semantic memory), structure building codelets, attention	Long-term memory includes production rules. Capacity is unlimited.	Long-term memory of Sigma based on a parallel rule system. And sigma long-term memory consists of Semantic memory, episodic memory, procedural memory, and image memory.

	codelets, procedural memory, and sensory-motor memory		
	SAL	ACT-R	Epic
	The SAL cognitive architecture is a combined model of ACT-R and Leabra, therefore the long-term memory feature of ACT-R is applicable for SAL as follows. SAL refers to declarative memory for long-term memory. Consist with items called "chunks" which have some number (usually less than three) of weighted slots and values. The number of activation functions controls the availability and recall speed of chunks. These functions include	ACT-R refers to declarative memory for long-term memory. Consist with items called "chunks" which have some number (usually less than three) of weighted slots and values. The number of activation functions controls the availability and recall speed of chunks. These functions include less-often-used activation decay that makes items harder to activate.	The declarative and working memory can be stored in an unlimited number of productions and propositions.

	less-often-used activation decay that makes items harder to activate.		
Goals	LIDA	Soar	Sigma
	There is no objection to options in the current situational model, options are converted to goals.	The goal hierarchy called universal sub-goals forms a problem state.	In the sigma model goals can be achieved by searching in problem spaces that are specified in terms of operators and sets of states.
	SAL	ACT-R	Epic
	Architectural goal stack track the goals. As goals are added to declarative memory as they are completed.	Architectural goal stack track the goals. As goals are added to declarative memory as they are completed.	In the production rules, there is a goal structure and can be encoded.
Learning	LIDA	Soar	Sigma
	Attentional learning is the capability of LIDA-based agents. Both instructionalist and selectionist learning occur in the conscious broadcast.	Learning, which is called chunking, occurs when a resolution is found. The impasse is reached if an operator cannot be selected. This is done using adding a new production to long-term memory.	Sigma includes long-term modifications to long term Memory was called learning. It has semantic, episodic, imaginal, and reinforcement learning mechanisms.

	SAL	ACT-R	Epic
	The SAL cognitive architecture is a combined model of ACT-R and Leabra, therefore the learning feature of ACT-R applicable for SAL as follows. Bidirectional interface with new symbol learning. Learning new productions and learning new chunks are included in symbolic learning. Weight adjustment for chunk slots and production strength adjustment for production utility is the sub-symbolic methods included.	Variety of learning mechanisms have in ACT-R. Learning new productions and learning new chunks are included in symbolic learning. Weight adjustment for chunk slots and production strength adjustment for production utility is the sub-symbolic methods included in ACT-R.	Any learning capability does not currently include EPIC.
Standard Cognitive Cycle	LIDA	Soar	Sigma
	LIDA consist of sequences of cognitive cycles. These cognitive cycles consist of	1. Input to the current state from the environment	Sigma consist of a cognitive cycle with phases of input, elaboration, adaptation, and output. It also breakout the

	planning, reasoning, volitional memory retrieval, imagining, day dreaming, etc. The model consists of phases of sensory input, perception and understanding, filtering, attention, broadcasting, action and learning, and effector output.	2. Operators propose a. All matching elaborations, operator proposals, and operator comparisons fire in parallel. b. Until nothing is left to fire, firing will continue. c. These firings have Support 3. An operator will decide 4. The operator will apply. a. This firing has O-support b. Other, based on the new state, I-supported rules may fire or retract 5. Output to the environment. In the basic case, the cognitive portion of the cycle takes approximately 60ms.	functionality of the two major phases of 1.Memory access, perception, and reasoning. 2.The decision, reflection, learning, affect, and attention. Also, sigma is based on tri-level functionality elegant control structure constructed in a nested manner: (1) single cognitive cycle based reactive capability (2) sequence of cognitive cycles based deliberative capability (3) impasses in decision making and processing at the meta-level based reflective capability

	SAL	ACT-R	Epic
	The SAL cognitive architecture is a combined model of ACT-R and Leabra, therefore standard cognitive cycle feature of ACT-R applicable for SAL as follows. 1. Independent buffers that each hold one chunk get input from the other processors. 2. With the contents of the buffers combined the current goal, may match several productions. 3. Which production rule fires determine by the production utility equation. 4. The production rule fires. Independent buffers, Output to the other processors will be generated.	1. Independent buffers that each hold one chunk get input from the other processors. 2. With the contents of the buffers combined the current goal, may match several productions. 3. Which production rule fires determine by the production utility equation. 4. The production rule fires. 5. Through the single-item independent buffers, Output to the other processors will be generated. The cognitive portion of this cycle	1. The working memory gets input from the perceptual module. There is no mechanism to convert attention. 2. Number of productions may match the contents of working memory. 3. Simultaneously fire all matched productions. 4. Motor processor gets the output. Resource conflicts are possible and must be avoided by the modeler. Generally takes 50ms for the cognitive portion of this cycle.

	The cognitive portion of this cycle approximately takes 50ms.	approximately takes 50ms.	
Model Creation	LIDA	Soar	Sigma
	LIDA tries to model the full range of activities from incoming stimuli to outgoing actions. Also tries to model the full range of cognitive processes in between incoming stimuli and outgoing actions.	The iterative defining and refining of the following involves constructing a Soar model: 1. States representations consist of • Attributes with values • Objects are simply values with additional attributes 2. Long term memory productions for • The initial state creation • Operator proposal • Evaluation of operator • Application of operator • Current state elaboration	Sigma was the enhancement of (1) the use of problem spaces to structure cognitive behavior; (2) the importance of the cognitive cycle two-phase structure; (3) the functional elegance of a nested three-layer model of control that layers reactivity within deliberation and deliberation within reflection; (4) the importance of a knowledge-compilation/automatization mechanism such as real-time behavior chunking in the complex reflective reasoning presence; (5) the push for uniformity; (6) approaching generic cognition by modeling human cognition with balancing the construction of functional AI systems;

		o This includes productions that check for failure or desired states or that provide are solution to an impasse • Removal of completed operators so that they may be proposed again	(7) the difficulty and importance of integrating capabilities implemented via knowledge on top of the architecture.
	SAL	ACT-R	Epic
	To create a SAL model, synthesize two architectures of ACT-R, and Leabra, therefore working memory feature of ACT-R applicable for SAL as follows: • Create declarative memory chunks production rules and • Setup parameters that are task-specific. The SAL consists of a lot more possible parameters than EPIC or Soar. Parameters need to	To create an ACT-R model, the outline of steps are as follows: • Create declarative memory chunks production rules and • Setup parameters that are task-specific. The ACT-R consists of a lot more possible parameters than EPIC or Soar. Parameters need to be adjusted for production utilities and	The following steps explain the epic model creation: • To perform the task creation of production rules or strategy, which is called the executive process; • Setup various processors task-specific parameters, especially the visual processor • If they are not specified in the task, select motor movement styles

	be adjusted for production utilities and declarative memory. This is needed for production conflict resolution and especially partial matching of declarative memory.	declarative memory. This is needed for production conflict resolution and especially partial matching of declarative memory.	

Table 1: Features of cognitive models

4.5.Synthesis of results

In here synthesis across six existing cognitive architectures: LIDA, ACT-R, Sigma, Soar, Leabra, and SAL. The synthesized standard model highlights loci of architectural agreement as well as identifying potential remaining incompleteness areas. It also explains key aspects of structure and processing, memory and content, learning, and perception, and motor. From those architectures, ACT-R provides a more realistic view of human psychology. Also, it explains international module, declarative module, visual module, manual module, goal buffer, retrieval buffer, visual buffer, manual buffer, a procedural module with matching, selection, and execution. It also explains the neural basis of those modules Borst et al. (2017).

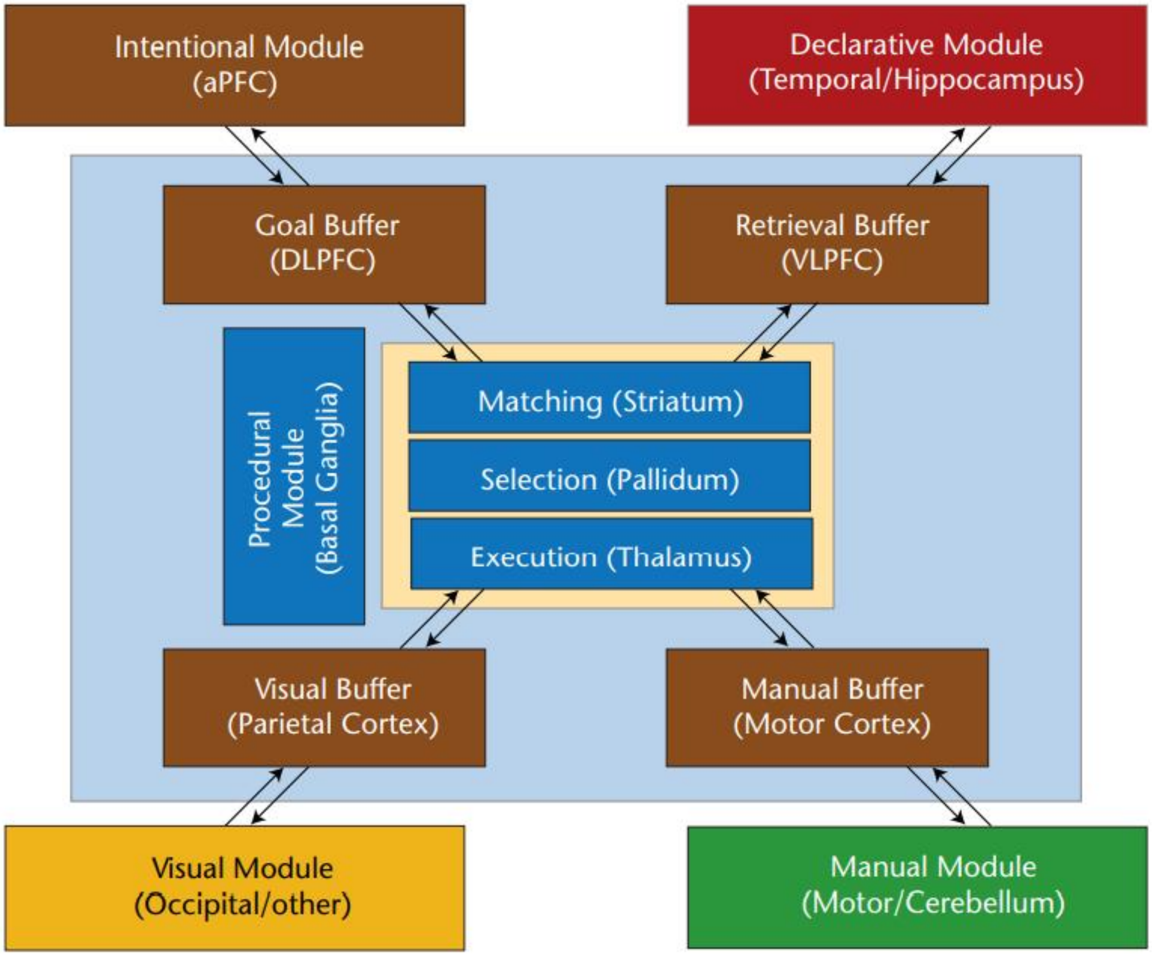

Figure 22: Adaptive Control of Thought—Rational (ACT-R) Cognitive architecture

Image credit: Borst et al. (2017)

Dancy, (2013) explains brain mapping of the ACT-R modules. It provided a more realistic view from a neural basis as well as a physiological basis.

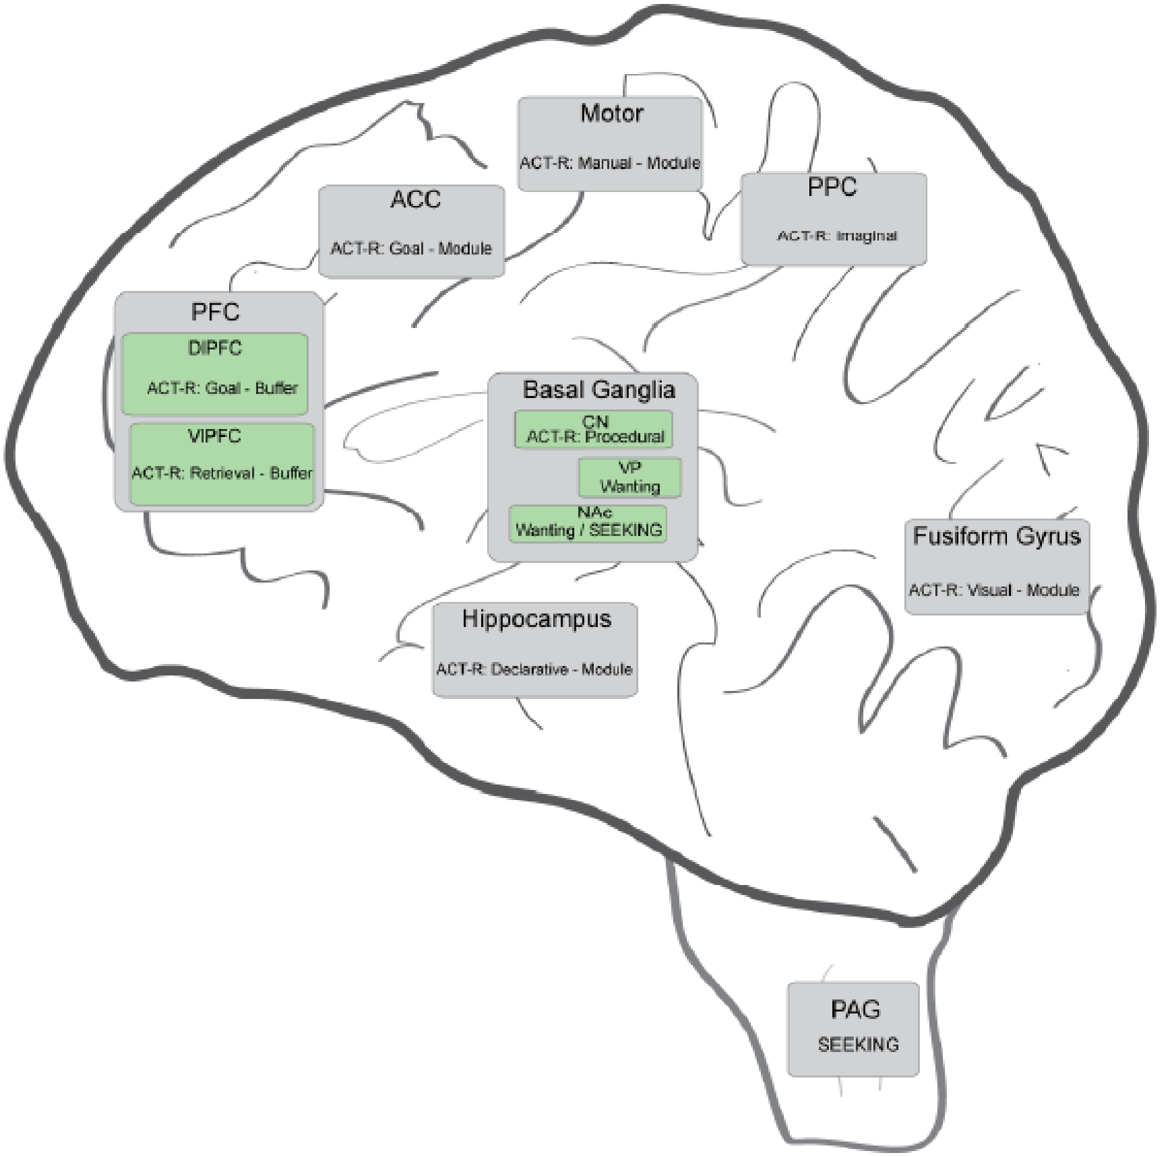

Figure 23: Key brain areas and ACT-R theories

Image credit: Dancy, (2013)

Temporal/Hippocampus, VLPFC, aPFC, DLPFC, occipital, parietal cortex, cerebellum, motor cortex, basal ganglia, striatum, pallidum, and thalamus was the associative neural areas of the brain.

Lowe and Ziemke, (2015) explain the behavioral organization of the mammalian brain in cognitive-affective architecture.

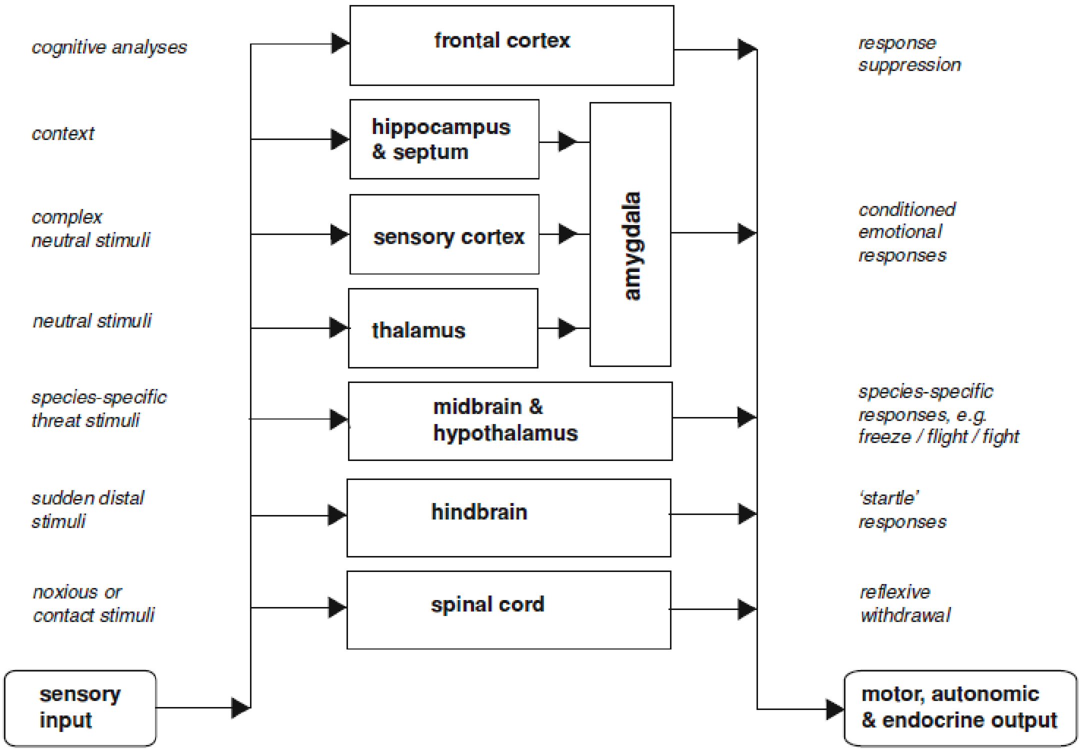

Figure 24: Layered architecture of the mammalian brain

Image credit: Lowe and Ziemke, (2015)

It also provides a more realistic view of brain organization related to the physiological view. It explains sensory inputs of cognitive analyses, context, complex natural stimuli, neutral stimuli, species-specific threat stimuli, and noxious or contact stimuli. Then explained those sensory inputs to brain structures of the frontal cortex, hippocampus & septum, sensory cortex, thalamus, amygdala, midbrain & hypothalamus, hindbrain, and spinal cord. Then it explained their output to motor, autonomic & endocrine structures.

Also, Lowe and Ziemke, (2015) explain interaction among the brain structures related to physiology. It explains the interaction of brain structures of the sensory cortex, hypothalamus, thalamus, amygdala, hippocampus, and working memory of mPFC and dIPFC.

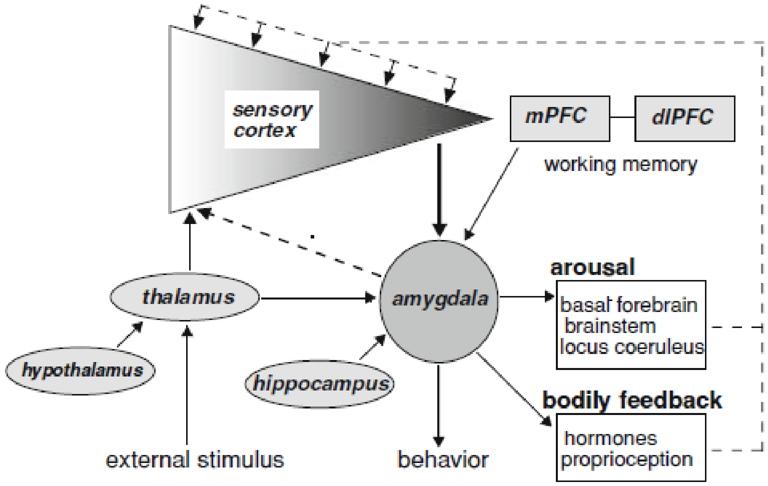

Figure 25: Interaction of mammalian brain

Image credit: Lowe and Ziemke, (2015)

Memory is also the main brain structure in cognitive architecture. O'Reilly et al., (2012)explain the structure of the hippocampal memory system and associated temporal lobe cortical structures.

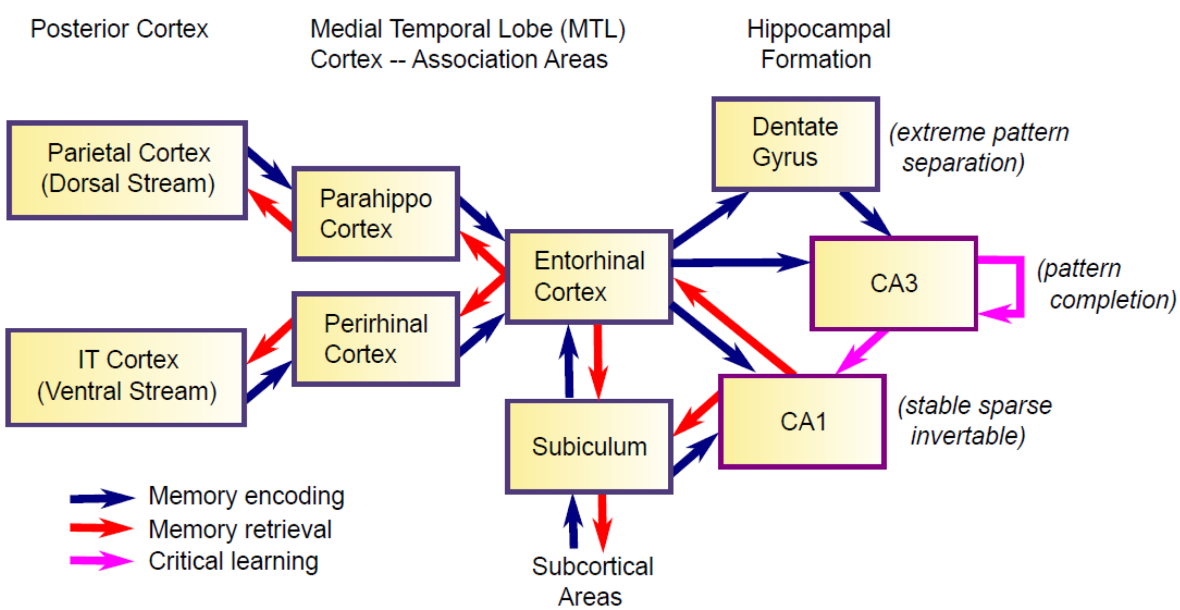

Figure 26: Structure of the hippocampal memory system

Image credit: O'Reilly et al., (2012)

It explained the memory process of memory encoding, memory retrieval, and critical learning related to brain structures of the partial cortex, it cortex, para hippo cortex, perirhinal cortex, entorhinal cortex, subiculum, dentate gyrus, CA1 and CA3 areas of the hippocampus.

O'Reilly et al., (2012) also explain the macro architecture of the mind. Main inputs are taken from the posterior cortex. Then active maintenance is done by frontal cortex; episodic memory provide by hippocampus; Main part of mind as action selection done by basal ganglia.

4.6.Risk bias across studies

Articles were accessed by two individual reviewers and there are no significant differences in the article reviewed by two revivers.

5.Discussion

5.1. Summary of evidence

In this study, 9 articles were selected for further analysis and synthesis to the achieving a better mental model with neurological circuit assemblies. These 9 articles include

- LIDA cognitive architecture
- Soar cognitive architecture
- Sigma cognitive architecture
- SAL cognitive architecture
- ACT-R (Adaptive control of thoughts – Rational) cognitive architecture
- EPIC cognitive architecture
- Leabra cognitive architecture
- Cognitive - affective architecture

- An embodied cognitive affective architecture

Those articles describe cognitive architectures in including mind functions as well as biological assemblies of those functions.

Article	Mind functions	Neural assemblies
LIDA cognitive architecture	Yes	No
Soar cognitive architecture	Yes	No
Sigma cognitive architecture	Yes	No
SAL cognitive architecture	Yes	Yes
ACT-R(Adaptive control of thoughts – Rational) cognitive architecture	Yes	Yes
EPIC cognitive architecture	Yes	No
Leabra cognitive architecture	Yes	Yes
Cognitive-affective architecture	Yes	No
An embodied cognitive-affective architecture	Yes	Yes

Table 2: Summary of cognitive architectures

From those selected architectures, considering the richness of mental functions and richness of neurological assemblies, features of the following architectures select for inclusion in the final model.

- ACT-R (Adaptive control of thoughts – Rational) cognitive architecture
- Leabra cognitive architecture
- An embodied cognitive-affective architecture

From those articles features included for the final model are as follows.

Article	Mind functions	Detailed neural circuits	Overall neural assembly
ACT-R(Adaptive control of thoughts – Rational) cognitive architecture	Yes	No	Yes
Leabra cognitive architecture	No	No	Yes
An embodied cognitive-affective architecture	No	Yes	No

Table 3: Mind model abstraction from cognitive architectures

This was achieved the objective of the neurological circuit assembly of mind model by systematic review and synthesizing existing cognitive architectures.

5.2. Limitations

This study consists of a systematic review according to PRISMA guidelines for developing a mental model with neural structures assemblies. To get the articles, the study use databases of PUBMED and Google scholar. Therefore the study is limited to available articles of those databases. Also, only English-language articles were considered. Although this systematic review as done according to PRISMA guidelines, the study use existing articles, therefore the final model will limit to features of only available cognitive architectures.

6.Conclusions

The study was done as a systematic review to find a model of a mind with neurological circuits assembled. To achieve this use the PRISMA guideline for systematic review. It uses databases of PUBMED, Google Scholar for search literature. Articles of9 cognitive architectures identified for explaining mind models.

Synthesis of cognitive architectures selects ACT-R functions as functions of the mind model. This includes an international module, declarative module, visual module, manual module, goal buffer, retrieval buffer, visual buffer, manual buffer, a procedural module with matching, selection, and execution.

International module related to aPFC. Declarative module related to temporal/hippocampus. Visual module related to the occipital lobe. Manual module related to motor/ cerebellum. Goal buffer related to DLPFC. Retrieval buffer related to VLPFC. Visual buffer related to the parietal cortex. Manual buffer related to the motor cortex. Procedural module related to basal ganglia. Matching related to the striatum. Selection related to pallidum. Execution related to the thalamus.

The mind takes the input of cognitive analyses, context, complex natural stimuli, neutral stimuli, species-specific threat stimuli, and noxious or contact stimuli. Then cognitive analyses process by frontal cortex; context processed by hippocampus & septum; complex natural stimuli process by sensory cortex; neutral stimuli process by thalamus; then the output of hippocampus & septum, sensory cortex, and thalamus processed by the amygdala; species-specific threat stimuli processed by midbrain & hypothalamus; sudden distal stimuli processed by hindbrain and noxious or contact stimulus processed by the spinal cord. Then it generated output to motor, autonomic & endocrine structures.

The central structure of the mind is the amygdala. It gets sensory inputs through the sensory cortex and external stimuli through the thalamus. Process those inputs it uses working memory as mPFC and dLPFC. After processing amygdala provides output as behavior.

Also, brain structures of the partial cortex, cortex, para hippo cortex, perirhinal cortex, entorhinal cortex, subiculum, dentate gyrus, CA1 and CA3 areas of the hippocampus are used for memory encoding, memory retrieval, and critical learning.

Overall posterior cortex process the sensory and semantic. Hippocampus work as episodic memory. Frontal cortex work as active maintenance of the thinking process. Basal ganglia work as action selection and the main part of the thinking process.

This reveals the mind model with neurological circuit assemblies to it. This is according to the current research done and base on this research it can enhance to find a more accurate mind model with neural structures assemblies.
